

# Metal Industry Indicators

## Indicators of Domestic Primary Metals, Steel, Aluminum, and Copper Activity

January 2015

---

**The primary metals leading index decreased sharply in December, and its 6-month smoothed growth rate moved into negative territory. The manufacturing sector accelerated during most of the year and underpinned the domestic primary metals industry. However, new orders for durable goods have decreased four of the last five months. This will likely have a negative effect on metals consumption in the near term. U.S. metal products exports generally remained flat or decreased in 2014 and imports increased. The rapidly declining metals price leading index growth rate indicates further decreases in most metal prices. U.S. metals inventories continued to climb, usually setting new record high levels each month. Most LME metal inventories, with the exception of aluminum, also continued to rise.**

The **primary metals leading index** decreased 1.7% to 165.9 in December from a revised 168.8 in November. The index's 6-month smoothed growth rate, a compound annual rate that measures the near-term trend, decreased to -1.3% from a revised 2.3% in November. A growth rate above +1.0% is usually a sign of an upward near-term trend for future metals activity, whereas a growth rate below -1.0% indicates a downward trend. For an explanation of these indexes and a definition of the primary metals industry, see page 10.

All four of the indicators that were available for the index's calculation decreased in December. A drop in the PMI, the Institute for Supply Management's purchasing managers' index contributed -0.7 percentage point to the overall decline in the leading index. However, the PMI is still above the threshold that denotes an increase in future manufacturing activity. The falling stock price index combining construction and farm machinery companies and industrial machinery companies contributed -0.4 percentage points. The deeply negative USGS metals price index growth rate also contributed -0.4 percentage point to the leading index. A slightly shorter average workweek in primary metals establishments contributed -0.2 percentage point. The primary metals leading index is subject to revision next month when the remaining four components become available.

The decline in the **primary metals leading index** growth rate suggests that activity in metals industry activity is likely to slow in the near future. The U.S. economy slowed in the final quarter of 2014 and this could decrease manufacturing activity in the months directly ahead. Decreased durable goods new orders will directly reduce metals consumption. In contrast, metals consumption from the construction sector could increase in 2015.

Nonresidential construction activity has been underpinned with some long term building projects, particularly manufacturing plants. Residential construction activity growth is likely to expand in 2015. Although apartment building activity is currently elevated, permits for future multi-unit building projects have declined. However, permits for single-family home construction reached a 7-year high in December. Moreover, weak global economic growth continued to limit exports of U.S. metals and metal products.

The **steel leading index** increased 0.3% to 115.5 in November from a revised 115.1 in October. Its 6-month smoothed growth rate increased to 1.4% from a revised 1.0% in October. Five of its nine indicators increased, but a rise in the inflation-adjusted M2 money supply growth rate made the largest positive contribution to the leading index. Upticks in car and light truck sales and the S&P stock price index for iron and steel companies in November also lifted the index. In contrast, the falling steel scrap price growth rate and a decrease in the index of new housing permits in November partially offset some of those gains. Growth in durable goods manufacturing had raised demand for steel products, but much of that demand had been met by imports. Although steel imports decreased in November and December, the steel import market share was near 30% for 2014. Although the steel leading index growth rate is still marginally above the threshold that signals an increase in industry activity, lower domestic demand and steel imports are likely to suppress growth in the U.S. steel industry.

The **copper leading index** increased 0.3% in November to 131.2 from a revised 130.8 in October. Its 6-month smoothed growth rate increased to 1.8% from a revised 1.3% in October. A

rebound in the S&P stock price index for building products companies posted the largest positive contribution to the copper leading index. In contrast, the falling copper price and the decrease in the index for new housing permits held the leading index back in November. Nevertheless, the copper leading index growth rate remained in the range that denotes an increase in U.S. copper industry activity growth.

## Negative Metals Price Leading Index Points To Further Metals Price Declines

The **metals price leading index** decreased 0.3% to 105.7 in November from a revised 106.0 in October. Its 6-month smoothed growth rate edged up to -4.1% in November from a revised -4.2% in October. The declining trade-weighted average exchange value of other major currencies against the U.S. dollar growth rate contributed -0.5 percentage point to the net decrease in the metals price leading index. A revised Organization for Economic Cooperation and Development (OECD) Total Leading Index growth rate increased in November, but remained below the threshold that denotes economic declines in most industrialized countries. It contributed 0.2 percentage point to the metals price

leading index. Changes in the yield spread between the U.S. 10-year Treasury note and the federal funds and the growth rate of the inflation-adjusted value of new orders for U.S. nonferrous metal products were so small that their contributions rounded to zero. The metals price leading index signals major changes in the growth rate of nonferrous metal prices an average of 8 months in advance.

The growth rate of the inflation-adjusted value of U.S. nonferrous metal products inventories, which is an indicator of supply and usually moves inversely with the price of metals, increased for a third consecutive month in November. As in most months, the value of metals inventories held in United States reached a new record high. However, LME inventory levels have been mixed. High metals inventories, along with the declining metals price leading index growth rate, point to further metal price decreases.

The business cycle and inventories are only two factors in metal price determination. Some other factors that affect prices include changes in metals production, speculation, strategic stockpiling, foreign exchange rates, and production costs.

**Note:** The components of the Leading Index of Metal Prices are the spread between the U.S. 10-year Treasury Note and the federal funds rate, and the 6-month smoothed growth rates of the deflated value of new orders for nonferrous metal products, the Organization for Economic Cooperation and Development (OECD) Total Leading Index, and the reciprocal of the trade-weighted average exchange value of the U.S. dollar against other major currencies. The Metal Industry Indicators (MII) Nonferrous Metals Price Index measures changes in end-of-the-month prices for primary aluminum, copper, lead, and zinc traded on the London Metal Exchange (LME). The steel scrap price used is the price of No. 1 heavy melting. Inventories consist of the deflated value of finished goods, work in progress, and raw materials for U.S.-produced nonferrous metal products (NAICS 3313, 3314, & 335929). Six-month smoothed growth rates are based on the ratio of the current month's index or price to its average over the preceding 12 months, expressed at a compound annual rate.

## Explanation

Each month, the U.S. Geological Survey tracks the effects of the business cycle on five U.S. metal industries by calculating and publishing composite indexes of leading and coincident indicators. Wesley Mitchell and Arthur Burns originated the cyclical-indicators approach for the economy as a whole at the National Bureau of Economic Research in the mid-1930s. Over subsequent decades this approach was developed and refined, mostly at the National Bureau, under the leadership of Geoffrey H. Moore.<sup>1</sup>

A business cycle can briefly be described as growth in the level of economic activity followed by a decline succeeded by further growth. These alternating periods of growth and decline do not occur at regular intervals. Composite indexes, however, can help determine when highs and lows in the cycle might occur. A composite index combines cyclical indicators of diverse economic activity into one index, giving decision makers and economists a single measure of how changes in the business cycle are affecting economic activity.

The indicators in the metal industry leading indexes historically give signals several months in advance of major changes in a coincident index, a measure of current metal industry activity. Indicators that make up the leading indexes are, for the most part, measures of anticipations or new commitments to various economic activities that can affect the metal industries in the months ahead.

Composite coincident indexes for the metal industries consist of indicators for production, shipments, and total employee hours worked. As such, the coincident indexes can be regarded as measures of the economic health of the metal industries.

The metal industry coincident indexes reflect industry activity classified by the U.S. Standard Industrial Classification (SIC) and the North American Industry Classification System (NAICS). Of the five metal industries, primary metals (NAICS 331) is the broadest, containing 25 different metal processing industries. Steel, aluminum, and copper are specific industries within the primary metals group.

The SIC was the main vehicle used by the U.S. Government and others in reporting industry economic statistics throughout most of the last century. Starting with the 1997 U.S. Economic Census, the U.S. Government began using the NAICS, which classifies economic data for industries in Canada, Mexico, and the United States. In general, metal industry indexes starting in 1997 begin to reflect the NAICS classification, while indexes for earlier years follow the SIC. Hence, composite indexes from 1997 forward are not entirely consistent with those of earlier years.

The largest change to primary metals because of the NAICS deals with other communication and energy wire manufacturing (NAICS 335929). Under NAICS, this manufacturing has been removed from primary metals and added to electrical equipment, appliance, and component manufacturing. Because monthly shipments and new orders for this wire are not available, the USGS is estimating their values from 1997 onward and adding them to the appropriate metal industry indicators and indexes to maintain consistency.

<sup>1</sup> Business Cycle Indicators, A monthly report from The Conference Board (March 1996).

There are other small changes to the primary metals industry because of the switch to the NAICS. Coke oven activity not done by steel mills, for example, is removed and alumina refining, a part of industrial inorganic chemical manufacturing under the SIC, is added. Because the historical trends of the composite indexes are not affected by these small changes, the USGS is not making specific adjustments to the indexes for them for the periods before and after 1997.

The metal industry leading indexes turn before their respective coincident indexes an average of 8 months for primary metals and 7 months for steel and copper.

The leading index of metal prices, also published in the Metal Industry Indicators, is designed to signal changes in a composite index of prices for primary aluminum, copper, lead, and zinc traded on the London Metal Exchange. On average, this leading index indicates significant changes in price growth about 8 months in advance.

The growth rate used in the Metal Industry Indicators is a 6-month smoothed growth rate at a compound annual rate, calculated from a moving average. Moving averages smooth fluctuations in data over time so that trends can be observed. The 6-month smoothed growth rate is based upon the ratio of the latest monthly value to the preceding 12-month moving average:

$$\left( \left( \frac{\text{current value}}{\text{preceding 12-month moving average}} \right)^{\frac{12}{6.5}} - 1 \right) * 100$$

Because the interval between midpoints of the current month and the preceding 12 months is 6.5 months, the ratio is raised to the 12/6.5 power to derive a compound annual rate.

The growth rates measure the near-term industry trends. They, along with other information about the metal industries and the world economy, are the main tools used to determine the outlook of the industries. A 6-month smoothed growth rate above +1.0% usually means increasing growth; a rate below -1.0% usually means declining growth.

**The next update for these indexes is scheduled for release on the World Wide Web at 10:00 a.m. EST, Friday, February 13. The address for Metal Industry Indicators on the World Wide Web is: <http://minerals.usgs.gov/minerals/pubs/mii/>**

The Metal Industry Indicators is produced at the U.S. Geological Survey by the National Minerals Information Center. The report is prepared by Gail James (703-648-4915; e-mail: [gjames@usgs.gov](mailto:gjames@usgs.gov)). The former Center for International Business Cycle Research, under the direction of Dr. Geoffrey H. Moore, and the former U.S. Bureau of Mines developed the metal industry leading and coincident indexes in the early 1990s. Customers can send mail concerning the Metal Industry Indicators to the following address:
